Momentum equation

Pressure gradient force:

The x component of the pressure gradient force acting on a fluid element.
Holton, 2004

Momentum equation in the inertial coordinate system

$$\frac{d\vec{v}}{dt} = -\frac{1}{\rho} \nabla p + \vec{g}$$

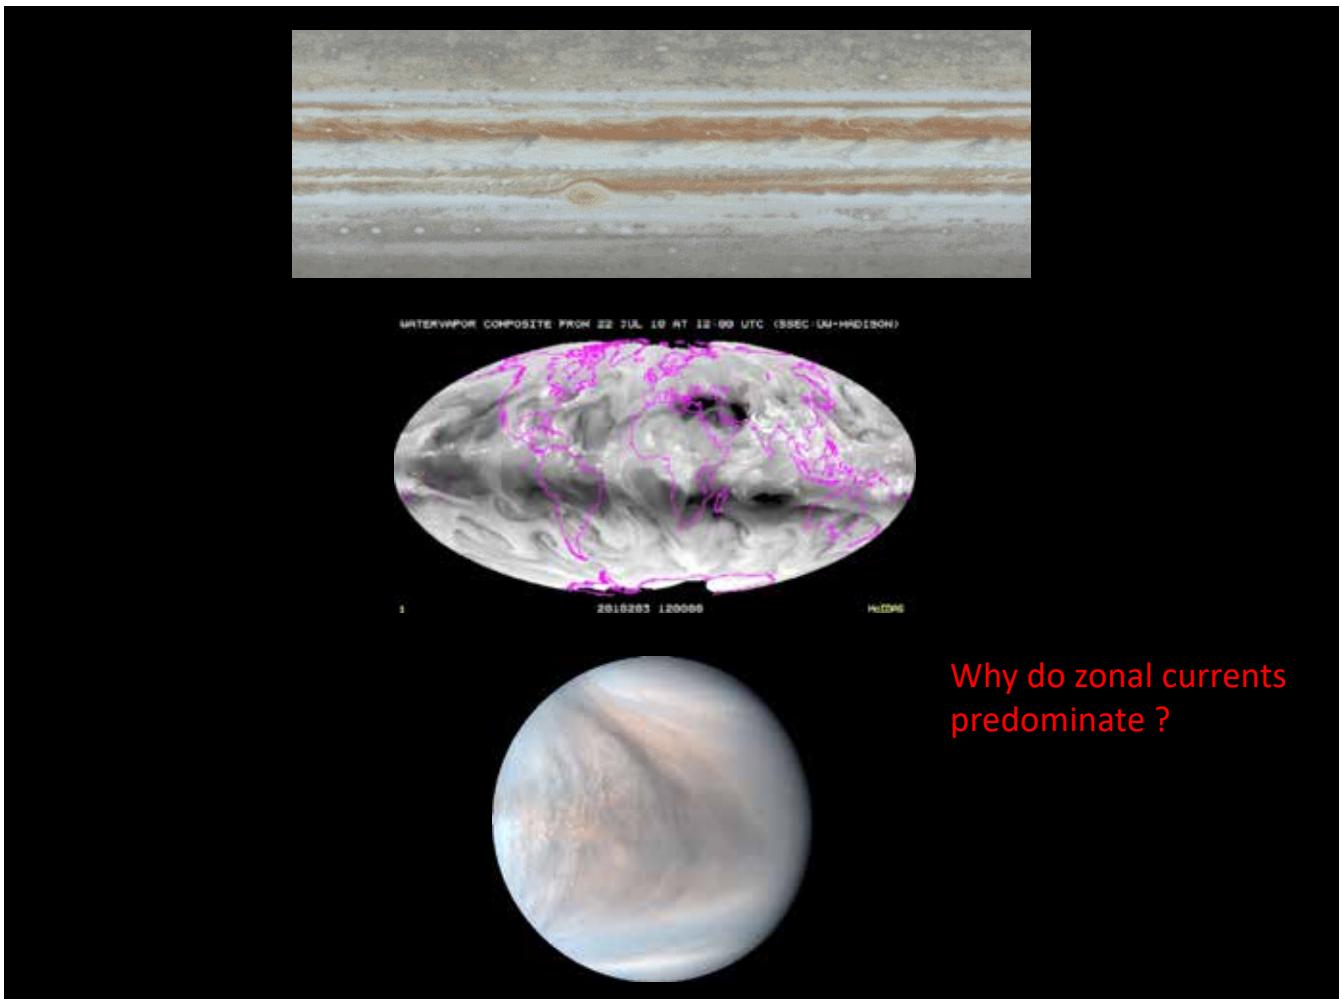

\vec{v} : velocity

t : time

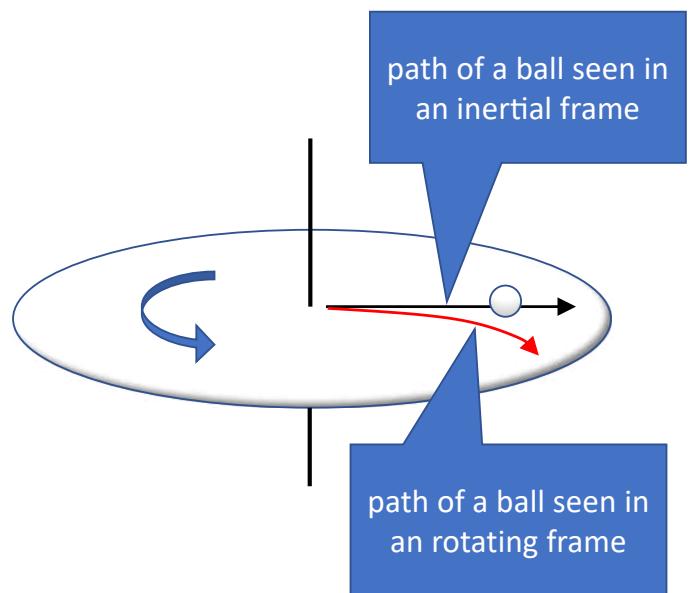

ρ : atmospheric density

p : atmospheric pressure

\vec{g} : gravity acceleration

Momentum equation in a rotating frame

Momentum equation in a rotating frame

Let us consider a frame rotating at an angular velocity $\vec{\Omega}$.

For a position vector \vec{r} , the relationship between the time derivative in the inertial frame d_r/dt and that in a rotating frame d/dt is

$$\frac{d\vec{r}}{dt} = \frac{d_r \vec{r}}{dt} + \vec{\Omega} \times \vec{r}$$

$$\therefore \vec{v} = \vec{v}_r + \vec{\Omega} \times \vec{r} \quad \vec{v}_r : \text{velocity in rotating frame}$$

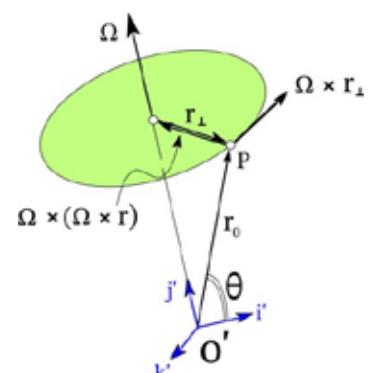

Similarly

$$\frac{d\vec{v}}{dt} = \frac{d_r \vec{v}}{dt} + \vec{\Omega} \times \vec{v}$$

Combining these, using $\vec{\Omega} \times (\vec{\Omega} \times \vec{r}) = -\vec{\Omega}^2 \vec{R}$ we have

$$\frac{d\vec{v}}{dt} = \frac{d_r \vec{v}_r}{dt} + 2\vec{\Omega} \times \vec{v}_r - \vec{\Omega}^2 \vec{R}$$

\vec{R} : vector from the rotational axis to the fluid position

Substituting the relationship into the momentum equation, one gets

$$\frac{d_r \vec{v}_r}{dt} = -2\vec{\Omega} \times \vec{v}_r - \frac{1}{\rho} \nabla p + \vec{g} + \Omega^2 \vec{R}$$

Hereafter the subscript r is omitted. The effective gravity acceleration is defined as the sum of \vec{g} and $\Omega^2 \vec{R}$. Then the momentum equation in the rotating frame is

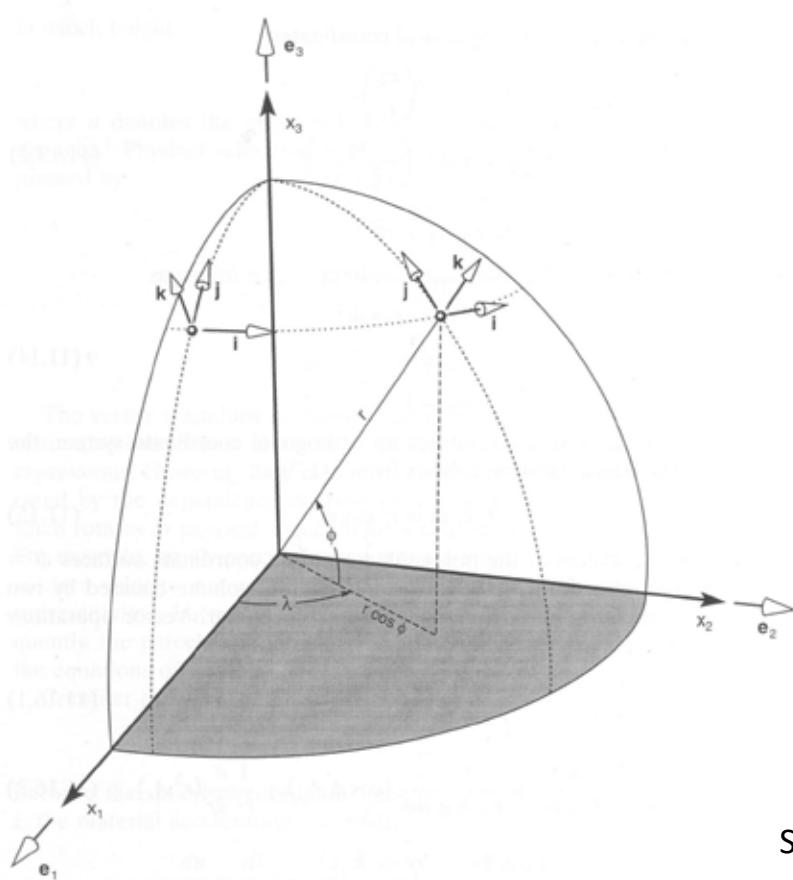

$$\frac{\partial \vec{v}}{\partial t} = -\vec{v} \cdot \nabla \vec{v} - 2\vec{\Omega} \times \vec{v} - \frac{1}{\rho} \nabla p + \vec{g}$$

Next we consider an expression in a Cartesian coordinate system on a spherical surface. Using the velocity component (u, v, w) in the unit vector system ($\vec{i}, \vec{j}, \vec{k}$),

$$\vec{v} = \vec{i} u + \vec{j} v + \vec{k} w \quad \vec{i} : \text{eastward}, \vec{j} : \text{northward}, \vec{k} : \text{upward}$$

Then

$$\frac{d\vec{v}}{dt} = \vec{i} \frac{du}{dt} + \vec{j} \frac{dv}{dt} + \vec{k} \frac{dw}{dt} + u \frac{d\vec{i}}{dt} + v \frac{d\vec{j}}{dt} + w \frac{d\vec{k}}{dt}$$

$$\begin{aligned}\frac{d\vec{i}}{dt} &= u \left(\frac{\tan \phi}{r} \vec{j} - \frac{\vec{k}}{r} \right) \\ \frac{d\vec{j}}{dt} &= -u \frac{\tan \phi}{r} \vec{i} - \frac{v}{r} \vec{k} \\ \frac{d\vec{k}}{dt} &= \frac{u}{r} \vec{i} + \frac{v}{r} \vec{j}\end{aligned}$$

Salby (1996)

Figure 11.2 Spherical coordinates: longitude λ , latitude ϕ , and radial distance r . Coordinate vectors $e_\lambda = \vec{i}$, $e_\phi = \vec{j}$, and $e_r = \vec{k}$ change with position (e.g., relative to fixed coordinate vectors e_1, e_2 , and e_3 of rectangular Cartesian coordinates).

Momentum equations (a : planetary radius)

$$\frac{du}{dt} = \left(2\Omega \sin \phi + \frac{u \tan \phi}{a} \right) v - \frac{uw}{a} - 2\Omega w \cos \phi - \frac{1}{\rho} \frac{\partial p}{\partial x}$$

$$\frac{dv}{dt} = - \left(2\Omega \sin \phi + \frac{u \tan \phi}{a} \right) u - \frac{vw}{a} - \frac{1}{\rho} \frac{\partial p}{\partial y}$$

$$\frac{dw}{dt} = \frac{u^2 + v^2}{a} - 2\Omega u \cos \phi - \frac{1}{\rho} \frac{\partial p}{\partial z} - g$$

$f = 2\Omega \sin \phi$: Coriolis parameter

The shaded terms are “metric” terms arising from the spherical geometry. These are small on the Earth. (Venus is exception)

When $dw/dt = 0$, the equation in the vertical direction reduces to the hydrostatic equilibrium:

$$\frac{\partial p}{\partial z} = -\rho g$$

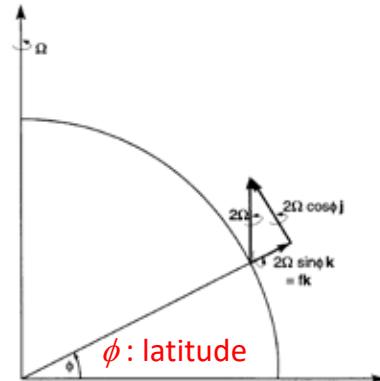

Figure 11.3 Planetary vorticity 2Ω decomposed into horizontal and vertical components.

Neglecting the metric terms and defining $\vec{v} = (u, v)$ as the horizontal component of the velocity, we have a set of governing equations:

$$\frac{\partial \vec{v}}{\partial t} = -\vec{v} \cdot \nabla \vec{v} - w \frac{\partial \vec{v}}{\partial z} - \bar{f} \vec{k} \times \vec{v} - \frac{1}{\rho} \nabla p \quad \text{horizontal momentum eq.}$$

$$\frac{\partial w}{\partial t} = -\vec{v} \cdot \nabla w - w \frac{\partial w}{\partial z} - \frac{1}{\rho} \frac{\partial p}{\partial z} - g \quad \text{vertical momentum eq.}$$

$$\frac{\partial \rho}{\partial t} = -\nabla \cdot (\rho \vec{v}) \quad \text{continuity eq.}$$

$$p = \rho R T \quad \text{state eq.}$$

$$\frac{\partial \theta}{\partial t} = -\vec{v} \cdot \nabla \theta - w \frac{\partial \theta}{\partial z} + \frac{1}{c_p} \left(\frac{p_s}{p} \right)^{R/c_p} \dot{H} \quad \text{thermodynamics eq.}$$

diabatic heating

\vec{k} : unit vector in the vertical direction

$f = 2\Omega \sin \phi$: Coriolis parameter

\dot{H} : diabatic heating rate ($J/m^3/s$)

Pressure coordinate

Large-scale atmospheric motions satisfy hydrostatic equilibrium.
In this case the pressure p can be used as the vertical coordinate:

$$p = p(z) \rightarrow z = z(p) \quad p : \text{pressure}, z : \text{altitude}$$

$\boxed{\omega} \equiv dp/dt$: vertical velocity in pressure coordinate
 $\boxed{\Phi}$: geopotential $d\Phi = gdz$

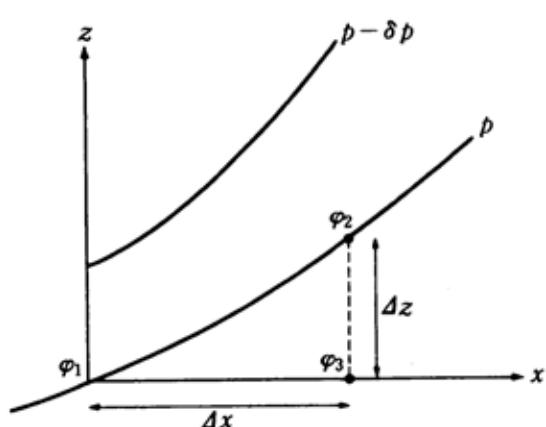

図 3.2 x - z 面内の断面。 小倉(1978)

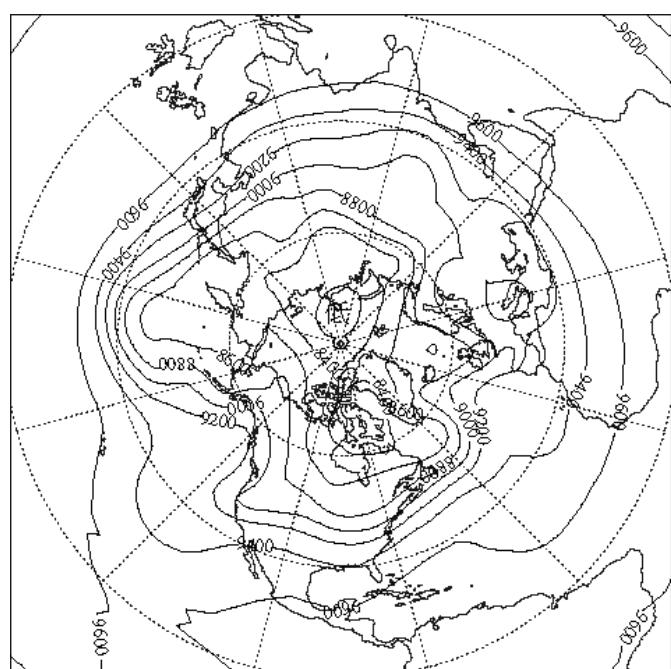

Approximate relationship between ω and w :

$$\omega \equiv dp/dt \sim -w/\rho g$$

Pressure gradient force in the momentum equation:

$$-\frac{1}{\rho} \nabla p \rightarrow -\nabla \Phi$$

300hPa, 2002/1/15

Primitive equations:

$$\begin{aligned}
 \frac{\partial \vec{v}}{\partial t} &= -\vec{v} \cdot \nabla \vec{v} - \omega \frac{\partial \vec{v}}{\partial p} - f \vec{k} \times \vec{v} - \nabla \Phi && \text{horizontal momentum eq.} \\
 \frac{\partial \Phi}{\partial p} &= -\frac{RT}{p} && \text{state eq. + hydrostatic equilibrium} \\
 \nabla \cdot \vec{v} + \frac{\partial \omega}{\partial p} &= 0 && \text{continuity eq.} \\
 \frac{\partial \theta}{\partial t} &= -\vec{v} \cdot \nabla \theta - \omega \frac{\partial \theta}{\partial p} + \frac{1}{c_p} \left(\frac{p_s}{p} \right)^{R/c_p} \dot{H} && \text{thermodynamics eq.}
 \end{aligned}$$

Geostrophic flow

For synoptic scale (>1000 km) motions in Earth's atmosphere:

horizontal scale $L \sim 1000$ km

pressure scale $P \sim 1000$ hPa

velocity scale $U \sim 10$ m/s

time scale $L/U \sim 10^5$ s

Coriolis parameter $f \sim 10^{-4}$ Hz

$$\cancel{\frac{\partial \vec{v}}{\partial t}} = \cancel{-\vec{v} \cdot \nabla \vec{v}} - \cancel{\omega \frac{\partial \vec{v}}{\partial p}} - \cancel{f \vec{k} \times \vec{v}} - \cancel{\nabla \Phi}$$

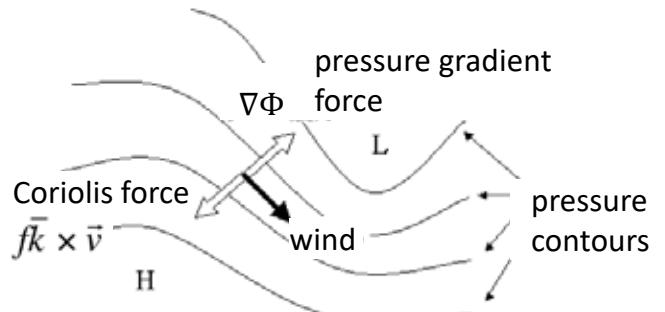

Coriolis force pressure gradient force
 $10^{-4} \quad 10^{-4} \quad 10^{-4} \quad 10^{-3} \quad 10^{-3} \quad (\text{m s}^{-2})$

The ratio between the acceleration (U^2/L) and the Coriolis force (fU)

$$R_o \equiv \frac{U}{fL} : \text{Rossby number} \text{ (around 0.1 on Earth, 10–100 on Venus)}$$

Geostrophic flow becomes a good approximation for small Rossby numbers

$$f\vec{k} \times \vec{v}_g = -\nabla\Phi$$

Definition of geostrophic flow

$$\vec{v}_g = \frac{1}{f} \vec{k} \times \nabla\Phi \quad \text{or} \quad u_g = -\frac{1}{f} \frac{\partial\Phi}{\partial y}, \quad v_g = \frac{1}{f} \frac{\partial\Phi}{\partial x}$$

Geostrophic flow is two-dimensional:

$$\nabla \cdot \vec{v}_g = 0$$

$$\omega = 0$$

Geostrophic flow is not a good approximation near the equator (f is small) or for scales $< O(100\text{km})$ (L is small) where $\text{Ro} (= U/fL)$ is large.

Thermal wind

Differentiating $f\vec{k} \times \vec{v}_g = -\nabla\Phi$ with respect to p and using $\frac{\partial\Phi}{\partial p} = -\frac{RT}{p}$, “thermal wind” relation is obtained:

$$\frac{\partial \vec{v}_g}{\partial p} = -\frac{R}{fp} \vec{k} \times \underline{\nabla T}$$

or

$$\frac{\partial u_g}{\partial p} = \frac{R}{fp} \frac{\partial T}{\partial y}$$

$$\frac{\partial v_g}{\partial p} = -\frac{R}{fp} \frac{\partial T}{\partial x}$$

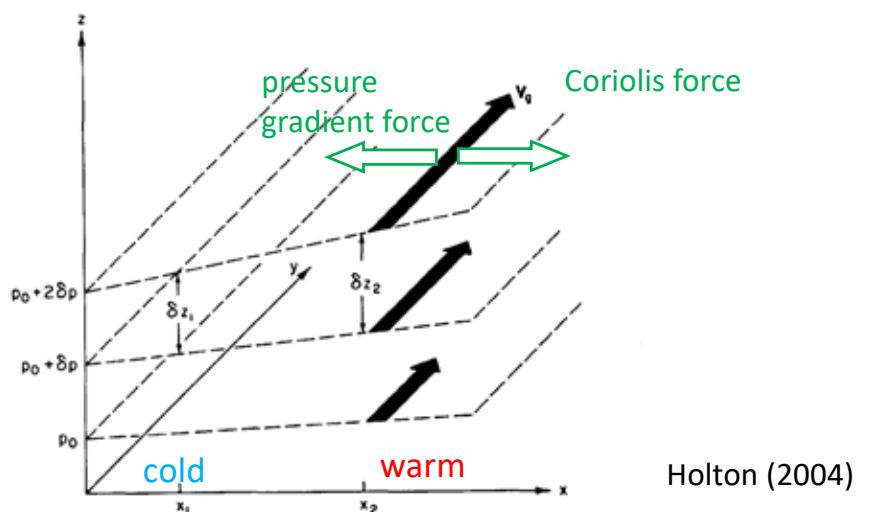

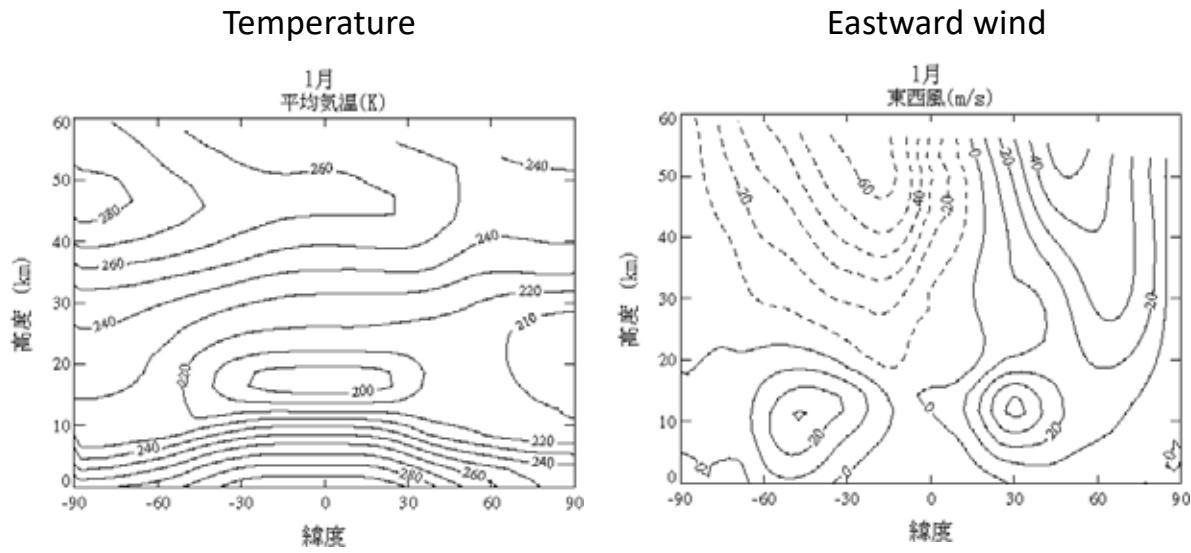

Fig. 3.8 Relationship between vertical shear of the geostrophic wind and horizontal temperature gradients. (Note: $\delta p < 0$.)

Rotational wind and divergent wind

The horizontal velocity vector can be expressed with the stream function ψ and the velocity potential ϕ :

$$\vec{v} = \underbrace{\vec{k} \times \nabla \psi}_{\text{Rotational wind}} + \underbrace{\nabla \phi}_{\text{Divergent wind}}$$

Rotational component is nondivergent

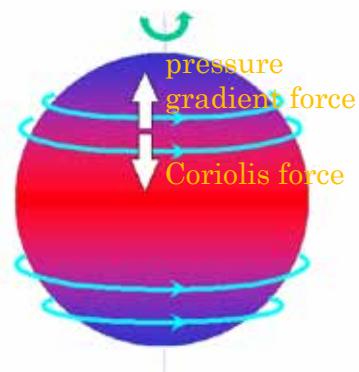

$$\nabla \cdot (\vec{k} \times \nabla \psi) = 0 \quad : \text{geostrophic flow, Rossby wave}$$

Divergent component is irrotational

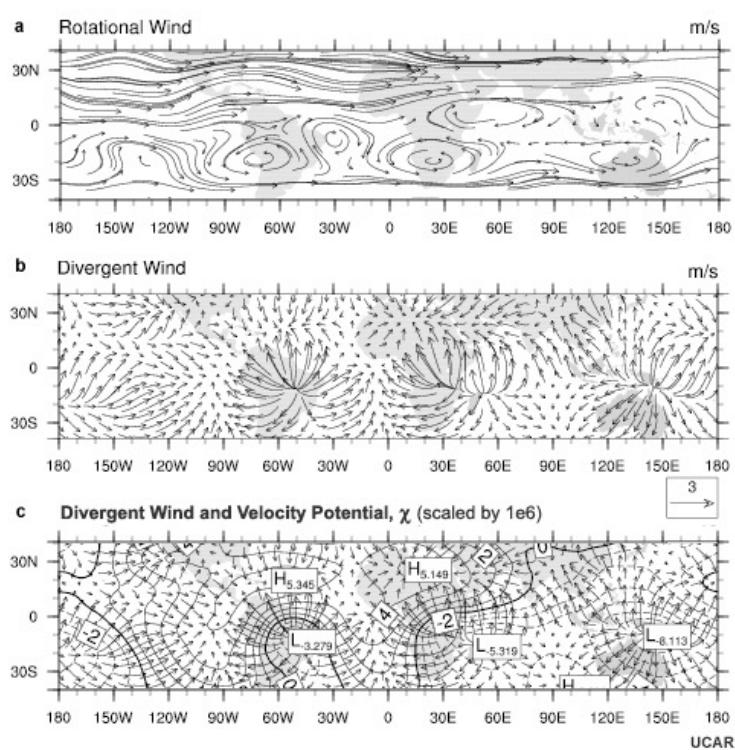

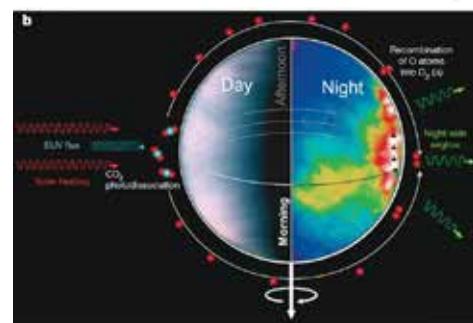

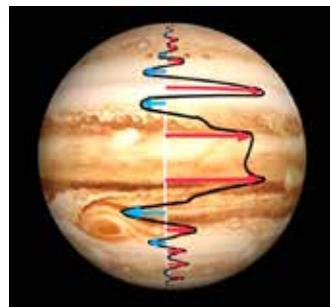

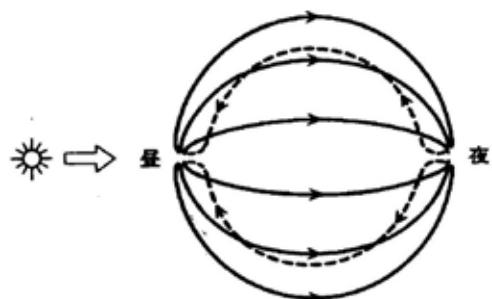

$$\nabla \times \nabla \phi = 0 \quad : \text{convection, gravity wave}$$

Atmospheric waves

Rossby wave (horizontal oscillation)

Gravity wave (vertical oscillation)

Salby (1996)

Vorticity

The *circulation* C about a closed contour is defined as the line integral along the contour of the component of the velocity vector that is locally tangent to the contour:

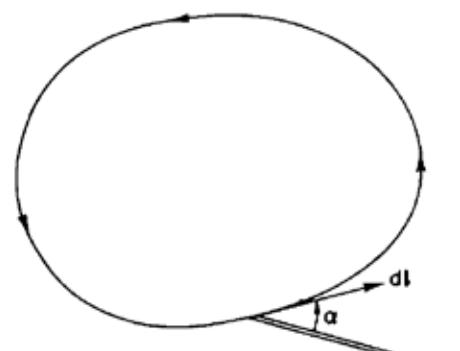

$$C = \oint_l \vec{v} \cdot d\vec{l} = \oint_l |\vec{v}| \cos \alpha dl = \iint_S (\nabla \times \vec{v}) \cdot \vec{n} dS$$

\vec{n} : unit vector normal to the surface

(Stokes' theorem was used.)

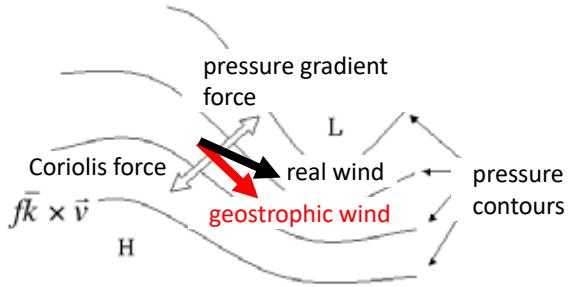

Dividing the circulation δC encircling a small area δS , and considering the limit $\delta S \rightarrow 0$, we get the *vorticity*:

$$\begin{aligned} \zeta &= \frac{\delta C}{\delta S} = (\nabla \times \vec{v}) \cdot \vec{k} \\ &= \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \end{aligned}$$

Holton (1992)

Quasi-geostrophic approximation

The real wind is divided into **geostrophic** wind and **ageostrophic** wind.

$$\vec{v} = \boxed{\vec{v}_g} + \boxed{\vec{v}_a}$$

$$\vec{v}_g \equiv \frac{1}{f_0} \vec{k} \times \nabla \Phi$$

$$\frac{v_a}{v_g} = O(R_o) \ll 1$$

$$R_o \equiv \frac{U}{fL}$$

The ratio of the magnitudes of the ageostrophic and geostrophic winds is the same order of magnitude as the Rossby number (around 0.1 in Earth's atmosphere)

Lagrangian derivative:

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \vec{v} \cdot \nabla + \omega \frac{\partial}{\partial p}$$

The advection term is approximated by advection by geostrophic wind:

$$\frac{d_g}{dt} \equiv \frac{\partial}{\partial t} + \boxed{\vec{v}_g} \cdot \nabla$$

Beta-plane approximation

The first-order Taylor series approximation of the Coriolis parameter f :

$$f = 2\Omega \sin \phi$$

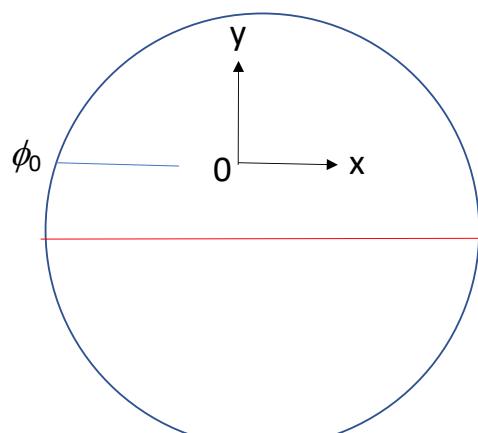

$$\sim 2\Omega [\sin \phi_0 + (\phi - \phi_0) \cos \phi_0]$$

$$= f_0 + \beta y$$

where

$$f_0 = 2\Omega \sin \phi_0$$

$$\beta = \frac{2\Omega}{a} \cos \phi_0 \sim \frac{df}{dy}$$

Mid-latitude beta-plane : $f = f_0 + \beta y$

Equatorial beta-plane : $f = \beta y$

Quasi-geostrophic vorticity equation

Introducing beta-plane approximation to the quasi-geostrophic Lagrangian derivative and retaining small quantities to the first order, the rate of change of the geostrophic wind is given by

$$\left(\frac{\partial}{\partial t} + \vec{v}_g \cdot \nabla \right) \vec{v}_g = -(f_0 + \beta y) \vec{k} \times (\vec{v}_g + \vec{v}_a) - \nabla \Phi \\ \sim -f_0 \vec{k} \times \vec{v}_a - \beta y \vec{k} \times \vec{v}_g \quad (1)$$

($\vec{v}_g \equiv \frac{1}{f_0} \vec{k} \times \nabla \Phi$ was used)

Since geostrophic wind is nondivergent ($\nabla \cdot \vec{v}_g = 0$), the continuity eq. is

$$\nabla \cdot \vec{v}_a + \frac{\partial \omega}{\partial p} = 0 \quad (2)$$

Operating rotation ($\nabla \times$) to (1) and using (2), we have the quasi-geostrophic vorticity equation.

Quasi-geostrophic vorticity equation:

$$\boxed{\frac{\partial \zeta_g}{\partial t} = -\vec{v}_g \cdot \nabla(\zeta_g + f) + f_0 \frac{\partial \omega}{\partial p}}$$

$$\zeta_g \equiv \frac{\partial v_g}{\partial x} - \frac{\partial u_g}{\partial y} = \frac{\nabla^2 \Phi'}{f_0} \quad : \text{geostrophic vorticity}$$

Vorticity changes with time through

- advection of absolute vorticity ($\zeta_g + f$) by geostrophic wind (\vec{v}_g)
- vertical divergence (horizontal divergence)

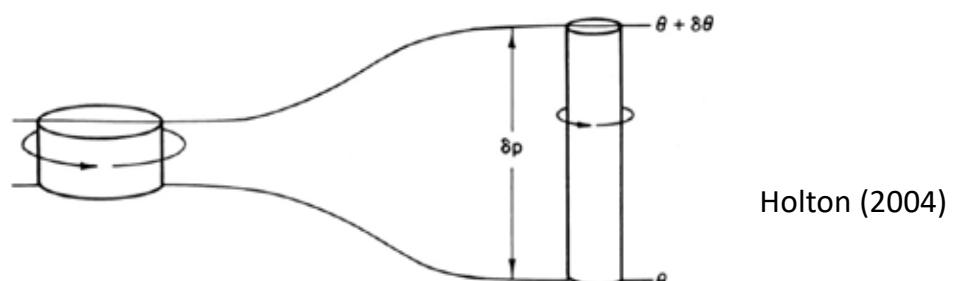

Fig. 4.7 A cylindrical column of air moving adiabatically, conserving potential vorticity.

Rossby wave

Let us consider a two-dimensional motion ($\omega = 0$)

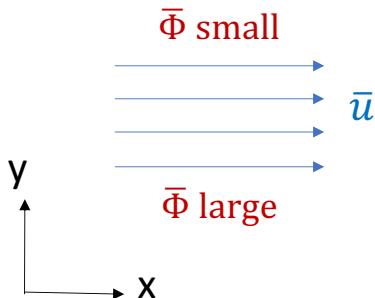

$$\left(\frac{\partial}{\partial t} + \vec{v}_g \cdot \nabla \right) (\zeta_g + f) = 0$$

→ Absolute vorticity ($\zeta_g + f$) is conserved along the geostrophic wind \vec{v}_g .

A basic state where a homogeneous zonal flow exists:

$$f\bar{u} = -\partial \bar{\Phi} / \partial y$$

$$\bar{\zeta}_g = 0$$

The deviation from the basic state is denoted by ()' :

$$\frac{\partial}{\partial t} \zeta_g + (\bar{u} + u'_g) \frac{\partial \zeta_g}{\partial x} + v'_g \frac{\partial \zeta_g}{\partial y} + v'_g \beta = 0 \quad (1)$$

The velocity and vorticity are related to the geopotential perturbation

$$\zeta_g = \frac{\nabla^2 \Phi'}{f_0}, \quad u'_g = -\frac{1}{f_0} \frac{\partial \Phi'}{\partial y}, \quad v'_g = \frac{1}{f_0} \frac{\partial \Phi'}{\partial x}$$

Substituting these into (1) and retaining first order terms only, we get

$$\frac{\partial}{\partial t} \nabla^2 \Phi' + \bar{u} \frac{\partial}{\partial x} \nabla^2 \Phi' + \beta \frac{\partial \Phi'}{\partial x} = 0$$

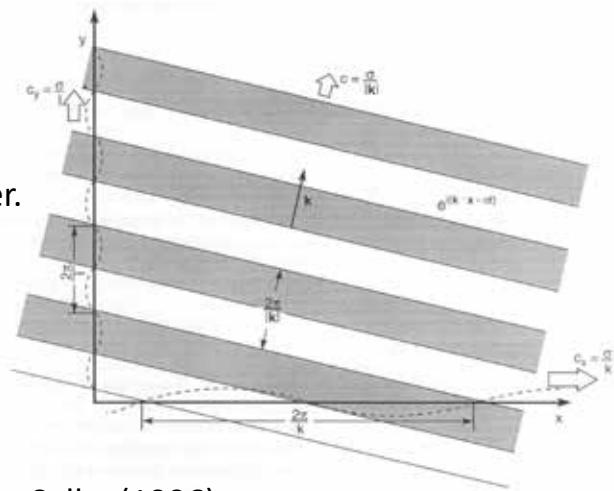

Assuming a wave solution $\Phi' = \hat{\Phi} \exp[i(kx + ly - kct)]$, the phase velocity of Rossby wave is obtained:

$$c - \bar{u} = -\frac{\beta}{k^2 + l^2}$$

k : zonal wavenumber
 l : meridional wavenumber
 c : zonal phase velocity

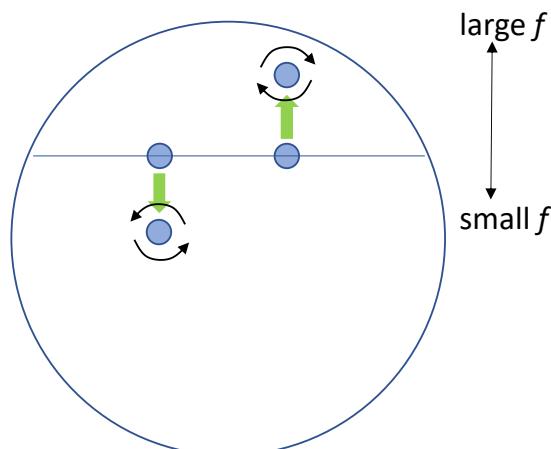

- Propagation opposite to the planetary rotation
- β effect (latitude variation of the Coriolis parameter f) is needed.
- Longer waves (smaller k) propagate faster.

The wave possesses angular momentum in the direction opposite to the planetary rotation

Salby (1996)

Propagation of Rossby waves

$$\left(\frac{\partial}{\partial t} + \vec{v}_g \cdot \nabla \right) (\zeta_g + f) = 0$$

$$f = 2\Omega \sin \phi$$

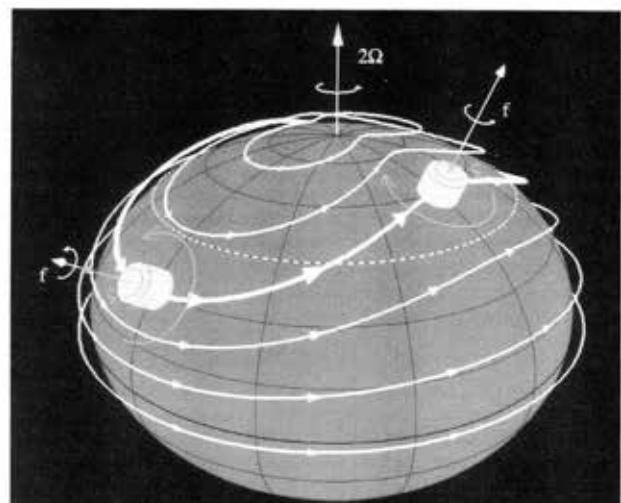

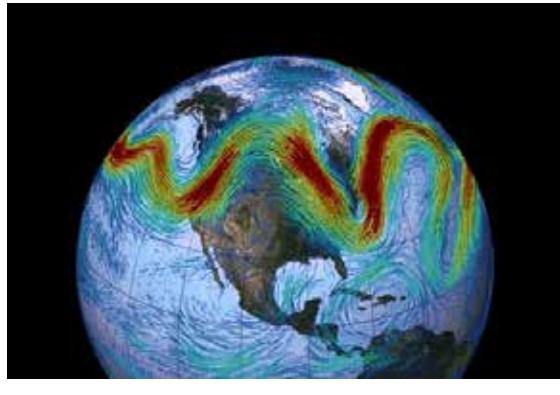

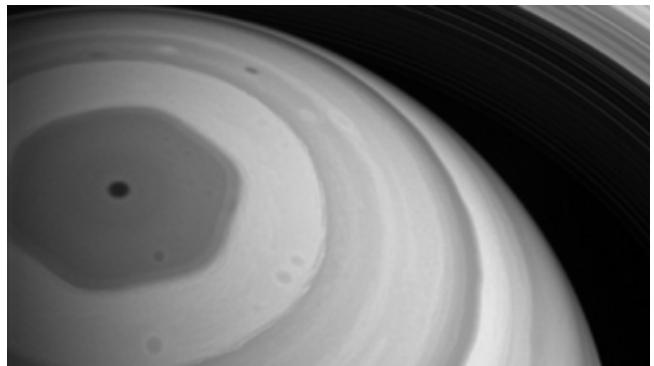

Figure 14.16 Schematic illustrating the reaction of an air parcel to meridional displacement. Displaced equatorward, an eastward-moving parcel spins up cyclonically to conserve absolute vorticity. Northward motion induced ahead of it then deflects the parcel's trajectory poleward back toward its undisturbed latitude. The reverse process occurs when the parcel overshoots and is displaced poleward of its undisturbed latitude.

Gravity wave

In Cartesian coordinates, without the assumption of hydrostatic equilibrium, the governing equations are:

$$\begin{aligned}
 \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + w \frac{\partial u}{\partial z} &= -\frac{1}{\rho} \frac{\partial p}{\partial x} && \text{horizontal momentum eq.} \\
 &&& (\text{x-axis only}) \\
 \frac{\partial w}{\partial t} + u \frac{\partial w}{\partial x} + w \frac{\partial w}{\partial z} &= -\frac{1}{\rho} \frac{\partial p}{\partial z} && \text{vertical momentum eq.} \\
 \frac{\partial \rho}{\partial t} &= -\frac{\partial(\rho u)}{\partial x} - \frac{\partial(\rho w)}{\partial z} && \text{continuity eq.} \\
 \frac{\partial \theta}{\partial t} + u \frac{\partial \theta}{\partial x} + w \frac{\partial \theta}{\partial z} &= 0 && \text{thermodynamics eq.} \\
 \theta &= \left[\frac{p}{\rho R} \left(\frac{p_s}{p} \right) \right]^{R/C_p} && \\
 && \text{T} &
 \end{aligned}$$

Equations for disturbances:

$$\begin{aligned}
 \bar{\rho} \frac{\partial u'}{\partial t} &= -\frac{\partial p'}{\partial x} && \text{horizontal momentum eq.} \\
 &&& (\text{x-axis only}) \\
 \bar{\rho} \frac{\partial w'}{\partial t} &= -\frac{\partial p'}{\partial z} - \rho' g && \text{vertical momentum eq.} \\
 \frac{\partial \rho'}{\partial t} &= -\bar{\rho} \frac{\partial u'}{\partial x} - \frac{\partial(\bar{\rho} w')}{\partial z} && \text{continuity eq.} \\
 \frac{1}{\bar{\theta}} \frac{\partial \theta'}{\partial t} + w' \frac{N^2}{g} &= 0 && \text{thermodynamics eq.} \\
 \rho' &= \frac{p'}{c_s^2} - \bar{\rho} \frac{\theta'}{\bar{\theta}} && \\
 c_s^2 &= \frac{c_p}{c_v} RT && c_s: \text{sound speed} \\
 N^2 &= g \frac{d \ln \bar{\theta}}{dz} && N: \text{buoyancy frequency}
 \end{aligned}$$

Assuming an isothermal atmosphere:

$$N^2 = g/c_p T$$

$$\bar{\rho}(z) = \rho_s \exp(-z/H)$$

Substituting the wave solution $w'(x,z,t) = \hat{w}(z)\exp[i(kx + \sigma t)]$ (σ : frequency) into the governing equations before, an equation for the vertical velocity w is obtained as

$$\frac{d^2(\bar{\rho}\hat{w})}{dz^2} + \frac{1}{H} \frac{d(\bar{\rho}\hat{w})}{dz} + \left[\frac{\sigma^2}{c_s^2} - k^2 + \frac{N^2 k^2}{\sigma^2} \right] \bar{\rho}\hat{w} = 0$$

Considering the amplitude growth with height in a stratified atmosphere, w is assumed to have the form

$$\hat{w}(z) = W(z) \exp(z/2H) \Leftrightarrow \bar{\rho}\hat{w}^2(z) \propto W^2(z)$$

Then the equation becomes

$$\frac{d^2W}{dz^2} + \left[\frac{\sigma^2}{c_s^2} - k^2 + \frac{N^2 k^2}{\sigma^2} - \frac{1}{4H^2} \right] W = 0$$

Assuming a wave solution $W \propto \exp(imz)$ (m : vertical wavenumber), the dispersion relation is obtained:

$$m^2 = \frac{\sigma^2}{c_s^2} - k^2 + \frac{N^2 k^2}{\sigma^2} - \frac{1}{4H^2}$$

Solutions for acoustic-gravity wave and internal gravity wave exist.

Approximate solution for internal gravity wave is

$$\sigma^2 = \frac{N^2 k^2}{k^2 + m^2 + \frac{1}{4H^2}} \quad \rightarrow \sigma < N$$

Structure of gravity wave

For large-horizontal scale waves (typical in planetary atmospheres),

$$\left| \frac{k}{m} \right| = \left| \frac{\sigma}{N} \right| \rightarrow \text{Long period waves have near-horizontal phase surfaces}$$

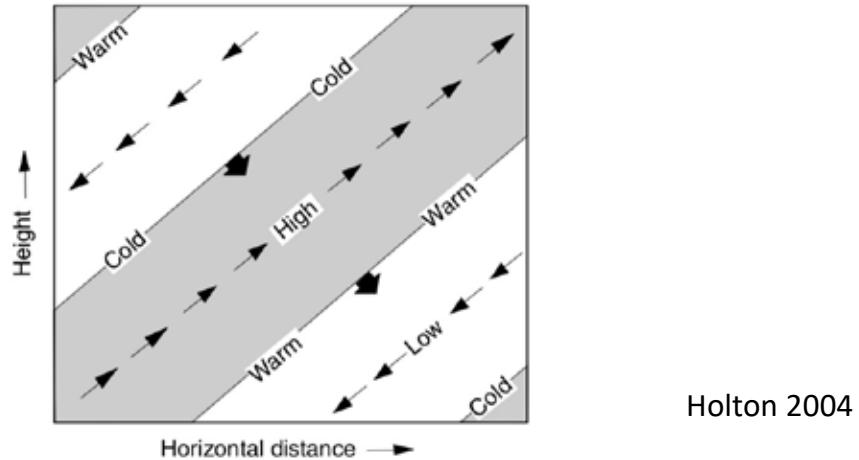

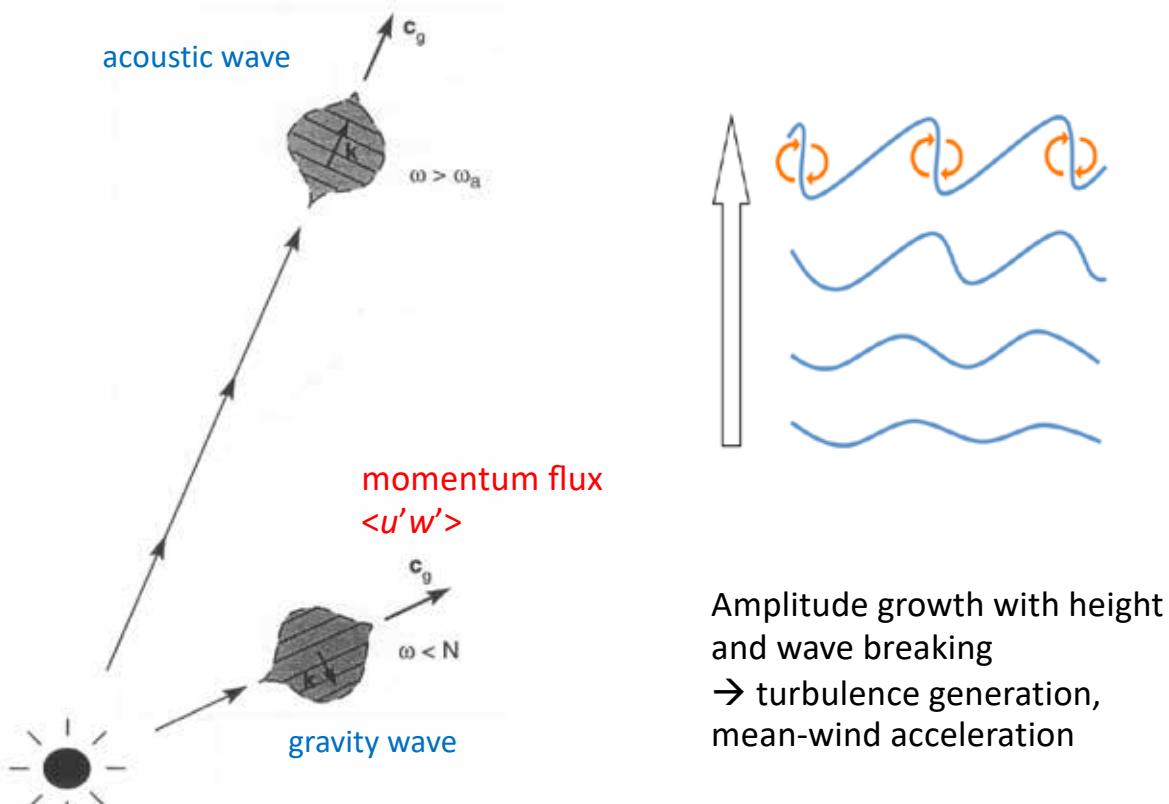

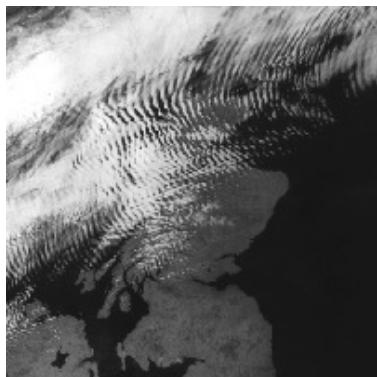

Fig. 7.9 Idealized cross section showing phases of pressure, temperature, and velocity perturbations for an internal gravity wave. Thin arrows indicate the perturbation velocity field, blunt solid arrows the phase velocity. Shading shows regions of upward motion.
